

Neisseria meningitidis IgG antibodies

General:

The test allows the determination of a specific immune response after vaccination. This test is not recommended for the diagnosis of an acute infection or screening for an earlier vaccination. Only a significant increase of the antibody level can point to a successful immune response after vaccination. For an interpretation anamnestic data regarding vaccination (when, how often) or diseases are necessary.

Material: 1 ml serum

TAT: 5-7 days*

Method: EIA

Units: RE/ml

Ref.- range: <31
